### Abstract

A new formula for determining the incident angle for which the light will be totally reflected from the prism is obtained here. That is, it can be estimated for what conditions we will get total reflection from any isosceles prism. There are some limitations in diversion angle of the prism in this formula, but more or less this formula is applicable for all type of isosceles prisms.

## INTRODUCTION

When light is incident upon a medium of lesser index of refraction the ray is bent away from the normal, so the exit angle is greater than the incident angle. Such reflection is commonly called "internal reflection". The exit angle will then approach 90° for some critical incident angle  $\theta_c$ , and for incident angles greater than the critical angle there will be total internal reflection, (Francis Jenkins and Harvey et al., 1981)

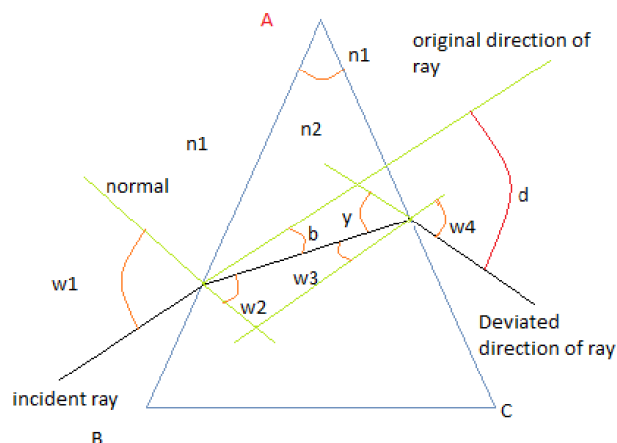

(a)Refraction; (b) Critical Angle; (c) Total internal reflection

In prism two surfaces are inclined at an angle  $\alpha$ .

Its refraction at the second surface as well as first surface follows Snell's law (Francis Jenkins and Harvey, 1981), so mathematically it can be expressed as:-

$$\frac{\sin w_1}{\sin w_2} = \frac{n_2}{n_1} = \frac{\sin w_4}{\sin w_3}$$

(d) Fig. Refraction in prism

The angle of deviation in first surface =  $\theta_1 - \theta_2$  and the angle of deviation in second surface =  $(\theta_4 - \theta_3)$ . Now let divide the one surface of the prism in two halves from middle. Consider the upper half as positive and lower half as negative portion.

Now let consider the ray of light falls on the “Positive” side of the prism in one surface. And let consider that the light falls on the base of the prism at an angle greater than critical angle. So “Total reflection” will take place from the base of the prism. And it will be diverted toward the second surface of the prism. So, by this way total reflection of light in any isosceles prism can be obtained.

**Theory**

Now,  $\angle ABC$  AND  $\angle ACB$  are same. A ray of light falls on Q in the considered positive side of the prism. Let, the incident angle is  $i_1$  and refractive angle is  $r_1$ . The two surfaces are inclined at an angle A.

$$\frac{\sin i_1}{\sin r_1} = \mu$$

$$\therefore \sin r_1 = \frac{\sin i_1}{\mu}$$

Now,  $D = (r_1 + r_2)$

$$i_1 = i_3$$

$$\Delta QOR \equiv \Delta SOR$$

$$\therefore QR = RS$$

Now,  $RS \parallel AB$  and  $QR$  cuts these two

$$\therefore \angle QRS = \angle RQB$$

$$\therefore 2r_2 = 90^\circ - r_1$$

$$\therefore 2r_2 + r_1 = 90^\circ$$

$$\therefore 2(D - r_1) + r_1 = 90^\circ$$

$$\therefore 2D - 90^\circ = r_1$$

$$\therefore \sin r_1 = \sin(2D - 90^\circ)$$

$$\therefore \frac{\sin i_1}{\mu} = \sin(2D - 90^\circ)$$

$$\therefore \sin i_1 = \mu \sin(2D - 90^\circ)$$

$$\therefore i_1 = \sin^{-1}[\mu \sin(2D - 90^\circ)]$$

$$= \sin^{-1}[\mu \sin(180^\circ - A - 90^\circ)]$$

$$= \sin^{-1}[\mu \cos A]$$

This formula is only valid for  $90^\circ \leq A \leq 48.2^\circ$   
[For  $\mu = 1.5$ ]

**Conclusion**

Thus by this formula the incident angles for which the ray of light will get totally reflected from the prism can be measured easily with some limitation. This formula will be helpful for any isosceles prism. This formula may be involved in future works.
